Additional output I get an error that there are no variables with which to make a prediction. But at the beginning of the notebook I declare the variables. What is the reason? A: I was facing the same issue, I was using Caffe v1.2.0 and I had to downgrade to Caffe v1.1.0 Q: How to use two servers in a VM on a physical server? I am setting up a database server and a webserver on the same server. They are both run by my ubuntu server. I want to be able to have both servers on in the VM that I have on the same physical server, and have the webserver be on port 80 and the database server on port 3306. When I put both in the VM, both servers run, but they both have port 3306, and port 80 is already taken by the webserver, so both of them run on port 80 in the VM. How can I fix this? Generally you would create a new Virtual Network Adapter, attach it to both the VM running the webserver and the VM running the database server, and use NAT to map between the 2 virtual adapters and the physical adapters. This is what I would recommend. If you were doing this for specific reasons, a VPN solution may work for you, but you would be mapping both of them to your main server and the primary difference is that you can use SSL connections on a VPN solution but not on a NAT solution. In either case, this is how you would setup your solution. Function template output_device_impl 82157476af
